

Setting Up and Using Amazon EFS

1. Create an EFS File System:

- Go to the AWS Management Console and search for "EFS" in the search box.
- Click on **Create file system**.
- Provide a name for the file system and customize the settings based on your requirements (such as performance mode, throughput mode, etc.).
- Choose the **VPC** and **Availability Zones** where you want the file system to be accessible.
- Make sure to enable **Backup** if you want automatic backups.
- Configure network settings by selecting the appropriate **security groups** and **access policies** for the file system.
- Review and **Create** the file system.

2. Mount the EFS File System on Instances:

- Use **Launch Templates** or manually create instances in different Availability Zones.
- Go to the EFS dashboard, select your file system, and then click on **Attach**.
- Choose the attachment method: either **DNS** or **IP**.
 - For DNS: You will use the EFS mount helper or NFS client.
 - Install the required package using: `sudo yum install amazon-efs-utils`
 - Create a directory where you want to mount the EFS: `sudo mkdir /efs`
 - Mount the EFS file system using: `sudo mount -t efs -o tls fs-0804e8441ed22cc47:/ /efs`
 - For IP: Use the IP address of the EFS file system in a similar mount command.

3. Verify the Mount:

- Check if the file system is mounted correctly using: `df -Th`
- Repeat the mount process for additional servers as needed.

4. Usage and Logging:

- Real-time servers can write logs to the EFS. This allows for centralized log management across different instances.
